COVER

The cover image shows organic photocatalysts with different compositions, dimensions (0, 1, 2), sizes, and crystallographic orientations that may be exploited to increase the sunlight utilization and charge separation efficiencies for solar water splitting. In article No. 2211010, Zhou *et al.* demonstrated that the physical and chemical processes of organic semiconductors are discussed from the perspective of light harvesting, photoexcited charge separation, and surface reactions. Typical organic semiconductor nanostructures for photocatalytic hydrogen evolution, such as perylene diimide, porphyrin, phthalocyanine, fullerenes, graphitic carbon nitride (g-C<sub>3</sub>N<sub>4</sub>), and other conjugated polymers, are systematically reviewed. Moreover, modification strategies for optimizing the optical and electrical properties at the molecular or aggregate level are presented.
